

AskQL

Ask your data anything. Get real answers in plain English.

A full-stack, multi-tenant text-to-SQL platform — no SQL required

100%

Query eval accuracy

AskQL

25+

Live production queries

0

Successful attacks

The problem

Great data. Locked behind a language most people don't speak.

Only engineers can query the database

Everyone else waits in line for a data request to get answered

Simple questions take hours

"What sold best last month?" shouldn't need a meeting with a data analyst

Manual SQL access is risky

One wrong query can expose or corrupt data with no safety net

The solution

Type a question. AskQL writes the SQL, runs it, and draws the chart — live.

"Which customers spent the most this year?"

Real SQL, instantly

Generated token-by-token and streamed live to the screen

Real results

Runs safely and returns actual rows from your data

Auto-generated chart

Picks the right visualization for the answer, no setup needed

How it works

Every question flows through the same safe, five-step pipeline

Nothing touches the database until it passes validation. Unsafe queries — wrong tables, banned commands, prompt injection — are rejected before they ever run.

Everything it does

Built as a real, complete product — not just a demo

Natural language to SQL

Ask in plain English, get a working query back

Live token streaming

Watch the SQL get written in real time, no waiting

Auto-generated charts

The right visualization is picked for every result

Upload your own data

Bring a CSV and query it the same way, instantly

Multi-tenant workspaces

Every user's data and history stays fully isolated

AI safety guardrails

Blocks unauthorized tables, unsafe SQL, prompt injection

Observability dashboard

Live usage, cost, and accuracy tracked for every query

Cloud-native deployment

Runs on Vercel and Google Cloud, built to scale

Built it. Then tried to break it.

Real security testing on the live app — not just a checklist

Ran an adversarial question against the live app

Asked it to hand over user password data — and it did

Found the real bug

A role with no explicit rules was defaulting to "allow everything" instead of "deny"

Fixed it at the root

Flipped the default to deny, then added a hardcoded safety net as backup

Verified the fix

Re-ran the exact same attack on the live site — this time, blocked

Under the hood

A modern, production-grade stack from front end to cloud

Frontend

React + Vite
Vercel hosting

Backend

FastAPI (Python)
Server-sent events

AI

OpenAI GPT-4o
Token-by-token streaming

Data

PostgreSQL (Supabase)
SQLite for uploads

Cloud & storage

Google Cloud Run
Google Cloud Storage

Safety

AST-based SQL validator
Role-based access control

Proven, not just promised

Measured on a live, deployed system — with a dashboard to prove it

100%

Accuracy on a 30-question golden test set

25+

Real questions answered in production

100%

Malicious queries blocked, zero data leaked

 **Sub-2s**

avg. query latency

 **\$0.005**

avg. cost per query

 **2**

user roles, fully isolated

 **Unlimited**

custom CSV datasets per user

How it's built

A simple, resilient architecture across three cloud platforms

Every request is validated before it reaches the database — safety enforced at the code level, not just in the UI.

Try it yourself

AskQL is live — ask it a question and watch it work in real time.
